

Criteria	Proficiency Level		
	Expert (4-5)	Proficient (2-3)	Emerging (0-1)
Innovative use of oneM2M	used 1 or more complex services such as group, announcement, pollingChannel, ...	use 1 or more complex features/attributes of basic resources: TimeSeries, FlexContainer, expiration times, max number of instances, etc.	used basic AE registration, containers, subscriptions
Use of appropriate communication protocols	Devices and applications use multiple different protocols, depending on the communication conditions. For example devices might use different protocols than applications. complex device to CSE to multiple application (complex application)	Devices and applications use other appropriate protocols for communication. Team describes why the different protocol is appropriate. multiple simple devices (e.g. sensor + actuator) to CSE to application	All devices and applications use http as the protocol for communication to the oneM2M CSE. single simple device (e.g. temp sensor) to CSE to application.
Innovative scenarios	IoT: Use oneM2M service functions instead of implementing functionalities on device or in applications. Includes all basic requirements (in box to the right) plus additional insights. Highlights benefits of using oneM2M.	IoT: Use oneM2M as a hub to manage communication between applications and devices. Includes all basic requirements: system/service overview, H/W, oneM2M resource design (if possible), oneM2M protocol usage (if possible) having pics, diagrams, texts	IoT: Use oneM2M as a "database" to store sensor data. Included all of the basic requirements with basic formatting and basic graphics. Limited discussion about oneM2M.
Quality of Article	Above average video production (not looking for expert quality, just a reasonable effort) that is enjoyable to watch and makes you want to continue reading the article (if it is at the beginning) or did a good job of tying things together (if it is at the end).	Used props (real, simulated, or virtual) to demonstrate the scenario of the project. Some basic video effects. Generally something you would normally watch to completion.	Basic video showing breadboard or experimental components. Decent to poor quality audio or lighting. Generally something you would not continue watching if you came across this on YouTube.
Quality of Video	Stand alone repository. Gives enough details to build, deploy and navigate source code directories. Can get a good understanding of the purpose of the repo without needing to read the hackster.io article, but includes a link to the article as well.	Basic README included. Build instructions included.	Bare minimum github repository with all source code (or some missing source code, based on visible inspection. i.e. it is clear that some files are missing)
Quality of Github	Article/video/repository represents a well written advertisement and endorsement of oneM2M.	Refers to oneM2M throughout the article, includes links to oneM2M resources and implementations.	Mentions oneM2M in title and introduction, but does not really direct a reader to oneM2M
Promotion of oneM2M	For interactions or discussions held in public forums (slack , github, etc, but not private emails) that demonstrated some aspects that you found beneficial or demonstrated good grasp of oneM2M.	For interactions that may have occurred in private channels (emails, phone calls) where team solicited support that demonstrated an attempt to gain greater understanding of oneM2M. e.g. can you explain the concepts of pollingChannel, group or announcement.	No interactions during the hackathon beyond administrative questions or configuration issues.
Judge points	In addition to the criteria to the right, team members can describe the methodology used to integrate oneM2M. The team members can describe why they would choose to use oneM2M to continue their project.	In addition to the criteria to the right, the team member can describe the benefits of using oneM2M.	Team members describe the resource tree structure. Team cannot explain the benefit of using oneM2M in their project.
Interview points	Used secure protocols in combination with <ACP>	Used multiple <ACP> and granted only permissions that were needed. Used separate <ACP> for devices/apps that have different needs for access to resources. Describes how privacy is appropriate for the use case and how it could be further developed in the demonstration application.	Used basic <ACP> that grants full access to all entities
Security and Privacy	Uses advanced features such as semantics (and SAREF) or SDT data models (TS-0023).	The data model uses flex containers to enable discoverability and uses queries to discover resources for their application use cases.	The data model uses opaque/proprietary data models, such as content instances. Labels are used to describe the data for discoverability.
Data Interoperability and Discoverability	Automated handover based on location, load, latency, or availability; preserves/rebuilds state, subscriptions, and security context; measures service interruption or data loss.	Controlled CSE handover; communications resume; required state/subscriptions are restored.	Manual or incomplete handover; state/data not synchronized; continuity not demonstrated.
CSE Handover & Service	Custom deployment scenario using project-specific geography/topology and oneM2M-MEC services; demonstrates orchestration across eligible hosts.	Deploys and registers an AE/CSE/MEC app or VM; integration and deployment procedure documented.	Primarily uses a preconfigured MEC environment with limited customization or orchestration.
oneM2M-MEC Application / VM Deployment	use custom oneM2M models that coordinates FL participants, datasets/tasks, status, and results; supports dynamic client selection and resilient multi-round training. The project uses the ESTIMED VM in this solution.	oneM2M distributes models/configuration and coordinates multiple clients; aggregates updates while data remains local. The project uses the ESTIMED VM in this solution.	Static/manual FL coordination with limited oneM2M integration or participant selection.
Federated Learning (TR-01)	Combines network/MEC/oneM2M location services to support mobility, handover, geofencing, placement, or policy; demonstrates event-driven behavior.	Obtains network location through MEC/oneM2M interworking and maps it into the application.	Uses device/GPS/cell location primarily as application-specific data with limited oneM2M location support.
Geolocation Services	Discovers, configures, and consumes multiple MEC services through oneM2M; demonstrates bidirectional MEC-oneM2M interaction.	Accesses at least one non-location MEC service through oneM2M.	MEC APIs are accessed directly; oneM2M operates largely independently.
MEC Services	Agent orchestrates multiple tools/MCP servers and executes complex oneM2M/MEC workflows with persistent state or advanced routing.	Structured agent performs multi-step tool operations, maintains state, validates results, and handles common errors.	Basic single-tool/MCP or prompt-response workflow with limited state, validation, or error handling.
AI Agents & MCP Integration
